

1.0 General Description

The G5137PT is a high performance AC/DC power supply controller which uses digital control technology to build peak current mode PWM flyback power supplies. The device operates in quasi-resonant mode to provide high efficiency along with a number of key built-in protection features while minimizing the external component count, simplifying EMI design and lowering the total bill of material cost. The G5137PT removes the need for secondary feedback circuit while achieving excellent line and load regulation. It also eliminates the need for loop compensation components while maintaining stability over all operating conditions. Pulse-by-pulse waveform analysis allows for a loop response that is much faster than traditional solutions, resulting in improved dynamic load response for both one-time and repetitive load transients. The built-in power limit function enables optimized transformer design in universal off-line applications and allows for a wide input voltage range. GlobalSemi's innovative proprietary technology ensures that power supplies built with the G5137PT can achieve both highest average active efficiency and have fast dynamic load response in a compact form factor in typical applications.

TYPICAL Application

Features

- ◆ No-load power consumption < 75 mW at 230 VAC along with fast dynamic load response
- ◆ Tight constant-voltage and constant-current regulation across line and load range
- ◆ Primary-side feedback eliminates opto-isolators and simplifies design
- ◆ Proprietary optimized 90 kHz maximum PWM switching frequency with quasi-resonant operation achieves best size, efficiency and common mode noise
- ◆ Adaptive Multi-mode PWM/PFM control improves efficiency
- ◆ No external loop compensation components required
- ◆ User-configurable 5-level cable drop
- ◆ Complies with EPA 2.0 energy-efficiency specifications with ample margin
- ◆ Built-in single-point fault protection features: output short-circuit protection, output over-voltage protection, over-current protection, current-sense-resistor fault protection.
- ◆ No audible noise over entire operating range

Applications

- Compact AC/DC adapter/chargers for media tablets and smart phones
- AC/DC adapters for consumer electronics

2.0 Products Information**2.1 Pin configuration**

Figure2.1: G5137PT Series (8 Lead DIP8 Package)

Pin#	Name	I/O	Description
1	VCC	Power Input	Power supply for the controller during normal operation. The controller will start up when VCC reaches 14.0 V (typical) and will shut down when the VCC voltage drops below 6.5 V (typical). A decoupling capacitor of 0.1 μ F or so should be connected between the VCC pin and GND.
2	CFG	Analog Input	Used to configure external cable drop compensation (CDC) at the beginning of start-up and provide accurate over-voltage protection during normal operation by sensing output voltage via auxiliary winding.
3	V _{SENSE}	Analog Input	Sense signal input from auxiliary winding. This provides the secondary voltage feedback used for output regulation..
4	I _{SENSE}	Analog Input	Primary current sense. Used for cycle-by-cycle peak current control and limit.
5/6	DRAIN	Output	HV MOSFET Drain Pin.The Drain pin is connected to the primary lead of the transformer
7/8	GND	Ground	Ground.

7. Theory of Operation

The G5137PT is a digital power switch which uses a new, proprietary primary-side control technology to eliminate the opto-isolated feedback and secondary regulation circuits required in traditional designs. This results in a low-cost solution for low power AC/DC adapters. The core PWM processor uses fixed-frequency Discontinuous Conduction Mode (DCM) operation at higher power levels and switches to variable frequency operation at light loads to maximize efficiency. Furthermore, GlobalSemi's digital control technology enables fast dynamic response, tight output regulation, and full featured circuit protection with primary-side control.

Referring to the block diagram in Figure 2.1, the G5137PT operates in peak current mode control. The digital logic control block generates the switching on-time and off-time information based on the output voltage and current feedback signal and provides commands to dynamically control the external MOSFET gate voltage. The I_{SENSE} is an analog input configured to sense the primary current in a voltage form. In order to achieve the peak current mode control and cycle-by-cycle current limit, the V_{IPK} sets the threshold for the I_{SENSE} to compare with, and it varies in the range of 0.23 V (typical) to 1.00 V (typical) under different line and load conditions. The system loop is automatically compensated internally by a digital error amplifier. Adequate system phase margin and gain margin are guaranteed by design and no external analog components are required for loop compensation. The G5137PT uses an advanced digital control algorithm to reduce system design time and increase reliability.

Furthermore, accurate secondary constant current operation is achieved without the need for any secondary-side sense and control circuits.

The G5137PT uses adaptive Multi-mode PWM/PFM control to dynamically change the MOSFET switching frequency for efficiency, EMI, and power consumption optimization. In addition, it achieves unique MOSFET quasi-resonant switching to further improve efficiency and reduce EMI. Built-in single-point fault protection features include over-voltage protection (OVP), output short-circuit protection (SCP), over-current protection (OCP), and I_{SENSE} fault detection.

GlobalSemi's digital control scheme is specifically designed to address the challenges and trade-offs of power conversion design. This innovative technology is ideal for balancing new regulatory requirements for green mode operation with more practical design considerations such as lowest possible cost, smallest size and high performance output control.

7.1 Start-up and Soft-start

When the VCC bypass capacitor is charged to a voltage higher than the start-up threshold $V_{CC(ST)}$, the ENABLE signal becomes active and the G5137PT begins to perform initial OTP check, followed by CDC configuration. Afterwards, the G5137PT commences soft-start function. During this start-up process an adaptive soft-start control algorithm is applied, where the initial output pulses will be small and gradually get larger until the full pulse width is achieved. The peak current is limited cycle by cycle by the I_{PEAK} comparator. If at any time the VCC voltage drops below under-voltage lockout (UVLO) threshold $V_{CC(UVL)}$ then the G5137PT goes to shutdown. At this time ENABLE signal becomes low and the VCC capacitor begins to charge up again towards the start-up threshold to initiate a new soft-start process.

Figure 7.1: Start-up Sequencing Diagram

7.2 Understanding Primary Feedback

Figure 7.2 illustrates a simplified flyback converter. When the switch Q1 conducts during $t_{ON}(t)$, the current $i_g(t)$ is directly drawn from rectified sinusoid $v_g(t)$. The energy $E_g(t)$ is stored in the magnetizing inductance L_M . The rectifying diode D1 is reverse biased and the load current I_O is supplied by secondary capacitor C_O . When Q1 turns off, D1 conducts and the stored energy $E_g(t)$ is delivered to the output.

Figure 7.2: Simplified Flyback Converter

In order to tightly regulate the output voltage, the information about the output voltage and load current need to be accurately sensed. In the DCM flyback converter, this information can be read via the auxiliary winding or the primary magnetizing inductance

G5137PT

Digital Green-Mode QR Primary-Side PWM Power Switch

(L_M). During the Q1 on-time, the load current is supplied from the output filter capacitor C_O . The voltage across L_M is $v_g(t)$, assuming the voltage dropped across Q1 is zero. The current in Q1 ramps up linearly at a rate of:

$$\frac{di_g(t)}{dt} = \frac{v_g(t)}{L_M} \quad (7.1)$$

At the end of on-time, the current has ramped up to:

$$i_{g_peak}(t) = \frac{v_g(t) \times t_{ON}}{L_M} \quad (7.2)$$

This current represents a stored energy of:

$$E_g = \frac{L_M}{2} \times i_{g_peak}(t)^2 \quad (7.3)$$

When Q1 turns off at t_o , $i_g(t)$ in L_M forces a reversal of polarities on all windings. Ignoring the communication-time caused by the leakage inductance L_K at the instant of turn-off t_o , the primary current transfers to the secondary at a peak amplitude of:

$$i_d(t) = \frac{N_P}{N_S} \times i_{g_peak}(t) \quad (7.4)$$

Assuming the secondary winding is master, and the auxiliary winding is slave,

Figure 7.3: Auxiliary Voltage Waveforms

The auxiliary voltage is given by:

$$V_{AUX} = \frac{N_{AUX}}{N_S} (V_O + \Delta V) \quad (7.5)$$

and reflects the output voltage as shown in Figure 7.3.

The voltage at the load differs from the secondary voltage by a diode drop and IR losses. Thus, if the secondary voltage is always read at a constant secondary current, the difference between the output voltage and the secondary voltage will be a fixed ΔV .

Furthermore, if the voltage can be read when the secondary current is small, ΔV will also be small. With the G5137PT, ΔV can be ignored.

The real-time waveform analyzer in the G5137PT reads this information cycle by cycle. The part then generates a feedback voltage V_{FB} . The V_{FB} signal precisely represents the output voltage under most conditions and is used to regulate the output voltage.

7.3 Constant Voltage Operation

After soft-start has been completed, the digital control block measures the output conditions. It determines output power levels and adjusts the control system according to a light load or heavy load. If this is in the normal range, the device operates in the Constant Voltage (CV) mode, and changes the pulse width (T_{ON}) and off time (T_{OFF}) in order to meet the output voltage regulation requirements.

If no voltage is detected on V_{SENSE} it is assumed that the auxiliary winding of the transformer is either open or shorted and the G5137PT shuts down.

7.4 Constant Current Operation

The constant current (CC) mode is useful in battery charging applications. During this mode of operation the G5137PT will regulate the output current at a constant level regardless of the output voltage, while avoiding continuous conduction mode. To achieve this regulation the G5137PT senses the load current indirectly through the primary current. The primary current is detected by the I_{SENSE} pin through a resistor from the MOSFET source to ground.

The G5137PT also provides a product option to disable the CC mode operation. If the power supply enters into the CC mode during normal operation, this product option will shut down the power supply. This feature serves as an over-load protection and can be used in certain adapter applications.

Figure 7.4: Power Envelope

7.5 Multi-Mode PWM/PFM Control and Quasi-Resonant Switching

G5137PT

Digital Green-Mode QR Primary-Side PWM Power Switch

The G5137PT uses a proprietary adaptive Multi-mode PWM /PFM control to dramatically improve the light-load efficiency and thus the overall average efficiency.

During the constant voltage (CV) operation, the G5137PT normally operates in a pulse-width-modulation (PWM) mode during heavy load conditions. In the PWM mode, the switching frequency keeps around constant. As the output load I_{OUT} is reduced, the on-time T_{ON} is decreased, and the controller adaptively transitions to a pulse-frequency-modulation (PFM) mode. During the PFM mode, the MOSFET is turned on for a set duration under a given instantaneous rectified AC input voltage, but its off time is modulated by the load current. With a decreasing load current, the off time increases and thus the switching frequency decreases.

When the switching frequency approaches to human ear audio band, the G5137PT transitions to a second level of PWM mode, namely Deep PWM mode (DPWM). During the DPWM mode, the switching frequency keeps around 25 kHz in order to avoid audible noise. As the load current is further reduced, the G5137PT transitions to a second level of PFM mode, namely Deep PFM mode (DPFM), which can reduce the switching frequency to a very low level. Although the switching frequency drops across the audible frequency range during the DPFM mode, the output current in the power converter has reduced to an insignificant level in the DPWM mode before transitioning to the DPFM mode. Therefore, the power converter practically produces no audible noise, while achieving high efficiency across varying load conditions.

As the load current reduces to very low or no-load condition, the G5137PT transitions from the DPFM to the third level of PWM mode, namely Deep-Deep PWM mode (DDPWM), where the switching frequency is fixed at around 1.2 kHz. The G5137PT also incorporates a unique proprietary quasi-resonant switching scheme that achieves valley-mode turn on for every PWM/PFM switching cycle, during all PFM and PWM modes and in both CV and CC operations. This unique feature greatly reduces the switching loss and dv/dt across the entire operating range of the power supply. Due to the nature of quasi-resonant switching, the actual switching frequency can vary slightly cycle by cycle, providing the additional benefit of reducing EMI. Together these innovative digital control architecture and algorithms enable the G5137PT to achieve highest overall efficiency and lowest EMI, without causing audible noise over entire operating range.

7.6 Variable Frequency Operation Mode

At each of the switching cycles, the falling edge of V_{SENSE} will be checked. If the falling edge of V_{SENSE} is not detected, the off-time will be extended until the falling edge of V_{SENSE} is detected. The maximum allowed transformer reset time is 110 μ s. When the transformer reset time reaches 110 μ s, the G5137PT shuts off.

7.7 Internal Loop Compensation

The G5137PT incorporates an internal Digital Error Amplifier with no requirement for external loop compensation. For a typical power supply design, the loop stability is guaranteed to provide at least 45 degrees of phase margin and -20 dB of gain margin.

7.8 Voltage Protection Features

The secondary maximum output DC voltage is limited by the G5137PT. When the V_{SENSE} signal exceeds the output OVP threshold at point 1 indicated in Figure 7.3 the G5137PT shuts down.

Although there is no pin available to directly sense the input voltage, the G5137PT uses an innovative proprietary digital control method to detect and analyze the switch ON time, which provides real-time indirect sensing and monitoring of the magnitude and shape of the DC bulk capacitor voltage. This enables the G5137PT to determine and distinguish various conditions of the AC input voltage such as brown-out, brown-in and unplug, and to take appropriate actions. When the AC input voltage drops to below normal operation range and the power supply input is still connected to the AC source, the G5137PT initiates brown-out protection and shuts down the power supply adaptively according to the power supply load condition. Meanwhile, a brown-in input voltage threshold is set with hysteresis. In the case of the power supply input being unplugged or disconnected from the AC source, the G5137PT continues to control the switching actions to discharge the DC bulk capacitor voltage to a safe level before shutting down the power supply. Also, the G5137PT monitors the voltage on the VCC pin, and the IC shuts down immediately when the voltage on this pin is below the UVLO threshold.

When any of these faults are met the IC remains biased to discharge the VCC supply. Once VCC drops below UVLO threshold, the controller resets itself and then initiates a new soft-start cycle. The controller continues attempting start-up until the fault condition is removed.

7.9 PCL, OCP and SRS Protection

Peak-current limit (PCL), over-current protection (OCP) or FastOCP and sense-resistor-short protection (SRSP) are features built-in to the G5137PT. With the I_{SENSE} pin the G5137PT is able to monitor the peak primary current. This allows for cycle-by-cycle peak current control and limit. When the peak primary current multiplied by the I_{SENSE} resistor is greater than 1.15 V, over-current is detected and the IC will immediately turn off the gate driver until the next cycle. The output driver will send out a switching pulse in the next cycle, and the switching pulse will continue if the OCP threshold is not reached; or, the switching pulse will turn off again if the OCP threshold is reached. If the OCP occurs for several consecutive switching cycles, the G5137PT shuts down.

If the I_{SENSE} resistor is shorted there is a potential danger that over-current condition may not be detected. Thus, the IC is designed to detect this sense-resistor-short fault after

G5137PT

Digital Green-Mode QR Primary-Side PWM Power Switch

start-up and shut down immediately. The VCC will be discharged since the IC remains biased. Once VCC drops below the UVLO threshold, the controller resets itself and then initiates a new soft-start cycle. The controller continues attempting to startup, but does not fully start-up until the fault condition is removed.

7.10 CDC Configuration

The G5137PT incorporates an innovative approach to allow users to configure cable drop compensation (CDC) externally. This configuration is only performed once. It is completed after the initial OTP check but before the soft-start commences. During the CDC configuration, the internal digital control block senses the external resistance value between the CFG pin and ground, and then sets a corresponding CDC level to allow the device to compensate for IR drop in the secondary circuitry during normal operation.

Figure 4.1 shows a simple circuit to set CDC level by connecting a resistor, R_{CDC} , from the CFG pin to ground. The G5137PT provides five levels of CDC configurations: 0, 75 mV, 150 mV, 300 mV, and 450 mV. Table 7.1 below shows the resistance range for each of the five CDC levels. In practice, it is recommended to select resistance in the middle of the range wherever possible.

The “Cable Comp” specified in Table 7.1 refers to the voltage increment at PCB end from no-load to full-load conditions in the CV mode, with the assumption that the secondary diode voltage drop can be ignored at the point when the secondary voltage is sensed. Also, the “Cable Comp” is specified based on the nominal output voltage of 5 V. For different output voltage, the actual voltage increment needs to be scaled accordingly. For example, for 12V, the corresponding five levels of CDC configurations would be: 0, 180mV, 360mV, 720mV, and 1080 mV.

To calculate the amount of cable compensation needed, take the resistance of the cable and connector and multiply by the maximum output current.

For each of the CDC levels, the internal V_{SENSE} -based OVP thresholds are different. Table 7.1 also lists the typical OVP thresholds for each CDC level.

Table 7.1 Recommended resistance range and corresponding CDC levels for 5V output

CDC Level	1	2	3	4	5
R_{CDC} Range (k Ω)	0-2.70	3.5 – 4.5	6.00 – 8.00	13.00–16.50	60.00-NC
Cable Comp (mV)	0	75	150	300	450
V_{SENSE} -based OVP Threshold	1.838	1.861	1.884	1.930	1.976

7.11 External CFG-Based Accurate OVP

In the G5137PT, the CFG pin can also be used to provide the external over-voltage

protection (OVP) besides fulfilling the CDC configuration. This external CFG-based OVP serves as a supplemental or extra protection in addition to the V_{SENSE} -based OVP. The circuit implementation can be found in Figure 7.5, where two resistors R_u and R_d form a

voltage divider to sense output voltage via auxiliary winding, with the tapping point connected to the CFG pin. During the CDC configuration the G5137PT does not send out

any drive signal at OUTPUT pin, and the switch Q1 remains in off-state. The resistors R_1 and R_2 are essentially connected in parallel since the bias winding is virtually shorted. Consequently, the paralleled resistance of R_u and R_d sets the CDC level. Meanwhile, during normal operation, the CFG pin reflects output voltage in real-time, in the similar fashion as the V_{SENSE} does at point 1 in Figure 7.3. The ratio of R_u to R_d sets the external OVP threshold.

The resistance values for the resistor divider, can be derived as follows.

First, for the given CDC level, the paralleled resistance of R_1 and R_2 should be within the range listed in Table 7.1:

$$R_{CDC} = \frac{R_1 \times R_2}{R_1 + R_2} \quad (7.8)$$

Second, during normal operation the voltage divider, R_1 and R_2 , sets the desired OVP threshold:

$$\left(\frac{N_{AUX}}{N_{SEC}} \right) \times V_{OVP} \times \left(\frac{R_2}{R_2 + R_1} \right) \geq V_{SD-TH(R)} \quad (7.9)$$

where N_{AUX} is the number of turns for the bias winding, N_{SEC} is the number of turns for the secondary winding, V_{OVP} is the desired OVP tripping point, and $V_{SD-TH(R)}$ is the internal comparator threshold (1.015 V typically) for OVP detection. The combination of Equations (9.6) and (9.7) leads to

$$R_1 = \left(\frac{N_{AUX}}{N_{SEC}} \right) \times R_{CDC} \times \left(\frac{V_{OVP}}{V_{SD-TH(R)}} \right)$$

$$R_2 = \left(\frac{R_1}{R_1 - R_{CDC}} \right) \times R_{CDC} \quad (7.10)$$

$$R_u = R_1; R_d = \frac{R_2 * R_{CFG}}{(R_{CFG} - R_2)}; \quad (7.11)$$

It is recommended the R_{CDC} value is taken as the median value of the resistance range

G5137PT

Digital Green-Mode QR Primary-Side PWM Power Switch

as given in Table 7.1, and R_u and R_d can then be readily derived from Equation (7.9).

It should be noted when the CFG pin is used to provide external OVP, an additional constraint will be applied to the resistance range given in Table 7.1. Since for the OVP configuration in Figure 7.5, a large negative voltage may occur to the auxiliary winding (V_x in Figure 7.5) during the switch on-time, which can cause a negative current flowing out of the CFG pin. Care needs to be taken to ensure R_u and R_d are large enough, so that the resulting negative current is less than the maximum allowed current, specified in Section 3.0.
